Mathematics for Machine Learning

Syllabus

November 2026

About the course

This course gives you the mathematics behind modern machine learning: linear algebra, multivariable calculus and optimization, probability, and statistics. It is the foundation for the courses that follow it, on machine learning, deep learning and reinforcement learning, and every topic is chosen because one of them uses it. We prove the main results, because understanding why a method works is what lets you adapt it when it does not; and we compute, by hand and with NumPy, because that is how the ideas become tools.

Format. 11 lectures of 3 hours, a 90-minute midterm exam after Lecture 6, and a 90-minute final exam after Lecture 11: 36 hours in total. The lectures explain the main ideas and prove the key theorems; the remaining proofs, extra examples and some sections are left for reading in the notes, as indicated below.

Prerequisites. Calculus of one variable (derivatives, integrals, Taylor expansions), comfort with algebraic manipulations, and basic Python. No previous course in linear algebra or probability is required: both are developed from the definitions.

What you will be able to do

- Work with vector spaces, linear maps and matrices, and use determinants, eigenvalues, the spectral theorem and the singular value decomposition to analyze them.
- Read and write tensor computations in Einstein notation and `np.einsum`, as in deep learning code.
- Compute gradients, Jacobians and Hessians of functions of vectors and matrices, and derive backpropagation with the chain rule.
- Derive gradient descent, explain its convergence and its dependence on the condition number, and solve constrained problems with Lagrange multipliers and the KKT conditions.
- Model uncertainty with random variables, multivariate Gaussians, Markov chains and Markov decision processes, and use the limit theorems and concentration inequalities to say how much data is enough.
- Fit models by maximum likelihood and by Bayesian inference, quantify uncertainty with standard errors, confidence intervals and tests, and recognize when these tools fail.

- Connect loss functions, regularizers and training procedures of machine learning to the mathematics behind them: cross-entropy and KL divergence, priors, the ELBO, and the Bellman equations.

Materials

- **Lecture notes** 1–4: Linear Algebra; Analytic Geometry; Vector Calculus and Optimization; Probability and Statistics. Each lecture ends with key takeaways, exercises and programming exercises. All four, with the two appendices, are also available as one book. The section numbers below refer to the notes (§4.8 is Section 8 of Lecture 4) and are the same in the book.
- **Practice problems** for each lecture, grouped by the sections of the notes, with a separate file of answers and hints. Problems marked *Mandatory* cover the core skills; do them before the next lecture.
- **Exercises and programming exercises** at the end of each lecture, the programming exercises in Python with NumPy. They are the homework of the course.
- **Appendices** for further reading: A. Topology, Differential Topology and Functional Analysis (after Lecture 3), and B. Measure-Theoretic Probability (after Lecture 4).
- **Sample exams** with solutions, in the format of the midterm and the final, and **approximate cheatsheets**: the cheatsheets handed out with the exams are shorter selections from them.

Assessment

Component	What it consists of	Weight
Homework	The exercises and the programming exercises at the end of the lecture notes	60%
Exams	The midterm and the final exam, 90 minutes each	40%
To pass	**at least 70% of the total**	

The practice problems are not graded: they come with answers, so that you can check your understanding and prepare for the exams.

Schedule at a glance

	Topic	Notes
1	Linear Algebra I: vector spaces and linear maps	§1.1–1.5
2	Linear Algebra I: matrices	§1.6.1–1.6.4
3	Linear Algebra I: determinants and matrix decompositions	§1.6.5–1.6.6
4	Linear Algebra I: rank, duality and quotient spaces	§1.7–1.9
5	Linear Algebra I: eigenvalues and tensors	§1.10–1.11
6	Linear Algebra II: geometry, spectral theorem, SVD and PCA	§2.1–2.8, 2.10, 2.11
Midterm exam (90 minutes): Lectures 1–6		
7	Calculus I: derivatives, the chain rule and backpropagation	§3.1–3.8, 3.15.2
8	Calculus II and Optimization	§3.9–3.12
9	Probability I–II: random variables, joint distributions and Gaussians	§4.1–4.6
10	Probability III: limit theorems, Markov chains and information	§4.7, 4.8.1–4.8.2, 4.13, 3.14.3
11	Statistical Inference: estimation, testing and Bayesian inference	§4.9, 4.10, 4.12.1–4.12.3, 4.14.1–4.14.2
Final exam (90 minutes): Lectures 7–11		

Lecture by lecture

For each lecture: what we cover in class, what to read on your own, the practice to do afterwards, and where the follow-up courses use the material (ML: machine learning, DL: deep learning, RL: reinforcement learning).

Lecture 1: Linear Algebra I — Vector Spaces and Linear Maps

Notes: Lecture 1, §1.1–1.5

In class. Number sets and fields. Vector spaces, including $\mathbb{R}^n$, matrices, polynomials and spaces of functions. Linear combinations, span, linear independence, bases and dimension (the exchange lemma). Linear transformations, kernel and image, isomorphisms and coordinates; differentiation and integration as linear maps. Subspaces.

Practice. Practice 1, sections 1–5.

Used in. The language of every later lecture: data points, parameters and functions are vectors, and models are maps between vector spaces.

Lecture 2: Linear Algebra I — Matrices

Notes: Lecture 1, §1.6.1–1.6.4

In class. The matrix of a linear map; matrix operations and composition. Row reduction and the reduced row echelon form. The inverse of a matrix and the Gauss–Jordan method; invertibility criteria. Matrices with respect to arbitrary bases. Special matrices (diagonal, triangular, symmetric, orthogonal), groups, $\mathrm{GL}(n)$ and $\mathrm{O}(n)$.

Practice. Practice 1, section 6 (matrix operations, row reduction, inverses, special matrices).

Used in. Linear layers $W\mathbf{x} + \mathbf{b}$ (ML, DL); solving linear systems for least squares (ML).

Lecture 3: Linear Algebra I — Determinants and Matrix Decompositions

Notes: Lecture 1, §1.6.5–1.6.6

In class. The trace and $\mathrm{tr}(AB) = \mathrm{tr}(BA)$. The determinant: cofactor expansion, row operations, the product rule, invertibility, and its geometric meaning as the factor by which areas and volumes change. The cofactor formula for the inverse.

Self-study. §1.6.6: block matrices and the Schur complement; the LU decomposition; the Woodbury identity, the Sherman–Morrison formula and the determinant lemma.

Practice. Practice 1, section 6 (trace, determinants, block matrices).

Used in. Gaussian densities and their conditionals (Lecture 9); Jacobian determinants of normalizing flows (DL); cheap updates of inverses in online and Bayesian learning.

Lecture 4: Linear Algebra I — Rank, Duality and Quotient Spaces

Notes: Lecture 1, §1.7–1.9

In class. Null space, column space and rank; the rank–nullity theorem. Dual spaces, dual bases and the dual map (the transpose); the double dual. Cosets and quotient spaces.

Self-study. Annihilators and the solvability of linear systems (Fredholm) in §1.8.4; the isomorphism theorems and the dimension formula in §1.9.3.

Practice. Practice 1, sections 7–9.

Used in. Gradients are linear functionals (Lectures 7–8); identifiability and rank deficiency in regression (ML); tensors (Lecture 5).

Lecture 5: Linear Algebra I — Eigenvalues and Tensors

Notes: Lecture 1, §1.10–1.11

In class. Eigenvalues, eigenvectors and eigenspaces; the characteristic polynomial, and trace and determinant as the sum and the product of the eigenvalues. Diagonalization, algebraic and geometric multiplicities, the Cayley–Hamilton theorem and the minimal polynomial. Powers of

matrices. Circulant matrices: the discrete Fourier transform diagonalizes convolutions. Tensors: the tensor product and its universal property, arrays of coordinates, multilinear forms, linear maps as tensors, the trace as a contraction, Einstein notation and `np.einsum`, tensor rank, and how tensors change under a change of basis.

Practice. Practice 1, sections 10–11.

Used in. Convolutional networks (DL); attention scores and batched computations in PyTorch, written as `einsum` (DL); exploding and vanishing gradients in recurrent networks, Markov chains and ARIMA models, which are all governed by powers of a matrix (DL, RL, ML).

Lecture 6: Linear Algebra II — Geometry, the Spectral Theorem, SVD and PCA

Notes: Lecture 2, §2.1–2.8, 2.10, 2.11

In class. Norms and inner products (quickly); symmetric positive definite matrices and the Cholesky decomposition; orthonormal bases, Gram–Schmidt and QR; orthogonal complements and the four fundamental subspaces. Orthogonal projections, least squares and linear regression, distances to hyperplanes. The spectral theorem, the Rayleigh quotient and Courant–Fischer. The singular value decomposition and its geometry, matrix norms, the Eckart–Young theorem, the pseudo-inverse, the condition number, and principal component analysis.

Self-study. §2.9 Rotations; §2.10.1 the graph Laplacian and spectral clustering.

Practice. Practice 2, all sections except 9 (Rotations).

Used in. Linear regression (ML); PCA, t-SNE and UMAP (ML); spectral clustering (ML); low-rank fine-tuning such as LoRA (DL); conditioning and optimizers (DL).

Midterm exam

90 minutes, after Lecture 6, on Lectures 1–2 (Lecture 1 and Lecture 2). Six open-ended problems: computations and short proofs. The midterm cheatsheet, with the definitions and theorems, is handed out with the exam; it is a shorter selection from the approximate midterm cheatsheet; no other notes and no calculators.

Lecture 7: Calculus I — Derivatives, the Chain Rule and Backpropagation

Notes: Lecture 3, §3.1–3.8 and §3.15.2

In class. Functions of several variables, limits and continuity; derivatives of one variable and Taylor polynomials (review). Partial derivatives, gradients, differentiability, directional derivatives and steepest ascent. Jacobians and the multivariable chain rule. Gradients with respect to matrices and Jacobi's formula for the determinant. Automatic differentiation: forward and reverse mode, computation graphs, backpropagation in a neural network, and vanishing gradients. Hessians and Taylor's theorem in several variables. Ordinary differential equations: gradient flow, and gradient descent as Euler's method.

Self-study. §3.13–3.14 vector fields and multiple integrals; §3.15.1 linear systems of ODEs; §3.16 flows and densities.

Practice. Practice 3, sections 1–8, and the gradient flow problems of section 15.

Used in. The derivation of backpropagation, autograd in PyTorch, and the analysis of vanishing and exploding gradients (DL).

Lecture 8: Calculus II and Optimization

Notes: Lecture 3, §3.9–3.12

In class. Critical points and the second-order test. Gradient descent, derived for the mean squared error; L-smooth functions, the descent lemma and line search; the behavior on quadratic functions and the role of the condition number; momentum and Newton's method. Convexity, strong convexity and the convergence rates of gradient descent; subgradients, the proximal gradient method and the lasso. Constrained optimization: Lagrange multipliers, the KKT conditions, duality and convex conjugates.

Practice. Practice 3, sections 9–12.

Used in. Gradient descent and SGD for linear and logistic regression (ML); L1 and L2 regularization as equivalent constrained problems (ML); momentum, RMSProp and Adam (DL); trust regions in TRPO (RL).

Lecture 9: Probability I–II — Random Variables, Joint Distributions and Gaussians

Notes: Lecture 4, §4.1–4.6

In class. Probability spaces, conditional probability, Bayes' theorem and independence. Random variables and their distributions (Bernoulli, binomial, geometric, Poisson, uniform, exponential, Gaussian), quantile functions and inverse transform sampling. Expectation and variance, tail sums, the inequalities of Markov, Chebyshev and Jensen. Joint, marginal and conditional distributions; covariance and correlation; the variance of a neural network layer and the Xavier and He initializations; conditional expectation and the law of total variance; conditional independence and graphical models; moment generating functions and Chernoff bounds. Random vectors and covariance matrices. The multivariate Gaussian, its marginals and conditionals, and the reparameterization trick.

Practice. Practice 4, sections 1–6.

Used in. Weight initialization and batch normalization (DL); naive Bayes and probabilistic classifiers (ML); variational autoencoders (DL); Gaussian processes (Lecture 11).

Lecture 10: Probability III — Limit Theorems, Markov Chains and Information

Notes: Lecture 4, §4.7, 4.8, 4.13, and Lecture 3, §3.14.3

In class. The law of large numbers, the central limit theorem and Hoeffding's inequality; convergence in distribution and the delta method. Monte Carlo methods and importance sampling; the score-function (REINFORCE) estimator of gradients of expectations. Markov chains, stationary distributions and convergence; the Metropolis algorithm. Markov reward and decision processes: the Bellman equations, policy evaluation and value iteration. Entropy, cross-entropy, the KL divergence and mutual information.

Self-study. The proofs of the limit theorems and of Hoeffding's inequality, and Slutsky's theorem (§4.7.1); rejection sampling (§4.7.2); the convergence of stochastic gradient descent (§4.7.3); Gibbs sampling (§4.8.1); §4.8.3 stationary time series and autoregressive models, which the ML course develops further; §4.15 stochastic differential equations, Langevin dynamics and diffusion models.

Practice. Practice 4, sections 7, 8 and 13 (the problems on time series are optional).

Used in. MDPs, Bellman equations, Q-learning (RL); UCB and MCTS via Hoeffding (RL); policy gradients via the score function (RL); off-policy learning and PPO via importance sampling (RL); MCMC in PyMC (ML); the cross-entropy loss, the KL terms of VAEs and RLHF, and contrastive learning (DL, RL).

Lecture 11: Statistical Inference — Estimation, Testing and Bayesian Inference

Notes: Lecture 4, §4.9, 4.10, 4.12, 4.14

In class. Estimators, bias, variance and the mean squared error; the method of moments; maximum likelihood (Bernoulli, Gaussian, linear and logistic regression as maximum likelihood); consistency, Fisher information and the Cramér–Rao bound (without proof); confidence intervals. Hypothesis tests, p-values and power; t-tests, and standard errors and t-tests for regression coefficients (the results and an example). Bayesian inference: priors, posteriors and conjugate priors, MAP estimation as regularization, and Bayesian linear regression. The evidence lower bound and the EM algorithm for Gaussian mixtures.

Self-study. §4.9.4 sufficiency and Rao–Blackwell; §4.9.6 exponential families and generalized linear models; §4.9.8 nonparametric estimation; §4.9.9 survival analysis and censored data; the Neyman–Pearson lemma and χ^2-tests in §4.10; the proofs in §4.10.1, the Gauss–Markov theorem and heteroscedasticity; §4.10.2 multiple testing; §4.10.3 the bootstrap and permutation tests; §4.11 cross-validation, classification metrics, generalization bounds and A/B testing; §4.12.4 Gaussian processes; §4.14.3–4.14.5 k-means, probabilistic PCA and variational autoencoders. The ML course returns to GLMs, survival analysis, heteroscedasticity, cross-validation and classification metrics.

Practice. Practice 4, sections 9, 10, 12 and 14 (the problems on survival analysis and heteroscedasticity are optional).

Used in. Logistic regression, confidence intervals and t-tests (ML); Bayesian regularization and PyMC (ML); Thompson sampling (RL); clustering with Gaussian mixtures (ML); the ELBO of VAEs (DL).

Final exam

90 minutes, after Lecture 11, on Lectures 7–11, using the linear algebra of Lectures 1–6 where needed. Six open-ended problems: computations and short proofs. The final cheatsheet is handed

out with the exam; it is a shorter selection from the approximate final cheatsheet; no other notes and no calculators (the problems give the numerical values you need).

How to work in this course

- **Before a lecture,** skim the sections of the notes listed for it.
- **After a lecture,** reread the sections, do the mandatory practice problems of the matching sections, and check your answers with the answer file only after you have tried. Then do as many of the other problems as you can; problems marked with a star are harder or more surprising.
- **Homework** consists of the exercises and the programming exercises at the end of the lecture notes, and makes up 60% of the grade, so start on it right after each lecture rather than before a deadline. In the programming exercises, implement the methods yourself with NumPy, and use library functions only to check your results.
- **Self-study sections** are part of the course material and complete the picture. The follow-up courses come back to several of them (time series, survival analysis, GLMs, heteroscedasticity, cross-validation, classification metrics, A/B testing, the bootstrap).
- **The appendices** are for students who want the rigorous foundations: Appendix A proves the results of Lecture 3 that need topology (the inverse and implicit function theorems, the existence of solutions of ODEs) and introduces manifolds, differential forms, Hilbert spaces and kernel methods; Appendix B builds probability on measure theory.
